How does the Periodic Table work?

The Periodic Table looks like this. It shows 118 different elements, and reveals which elements are similar to each other. Each box represents one element.

1 H HYDROGEN 1																	2 He HELIUM 4						
3 Li LITHIUM 7	4 Be BERYLLIUM 9																	5 B BORON 11	6 C CARBON 12	7 N NITROGEN 14	8 O OXYGEN 16	9 F FLUORINE 19	10 Ne NEON 20

Lift the flap to see them.											

Mendeleev was the first chemist to find a way to order the elements. He weighed equal amounts of different elements, and arranged them according to how heavy their atoms were.

An element's code name, called its **chemical symbol**, can be quite different from its name.

My name is **TUNGSTEN** but my symbol is **W**.

92 elements are found in nature.

The Periodic Table is used in every country, and the code names are the same in every language, even when their full names are different.

This group of elements is in a small grid underneath, to make the table easier to read.

A lot of the elements not found in nature are named after famous scientists. Lift the flaps to find out who.

The elements of life

A few elements in the table are known as **non-metals**. They are all essential to life on Earth. From the air you breathe to the water you drink, they're in you and in everything around you.

The non-metals are split across the table.

HYDROGEN is the most abundant element in the Universe.

HYDROGEN is the lightest element. It used to be used to keep airships called zeppelins in the air.

All life on Earth is based on CARBON.

78% of the Earth's atmosphere is NITROGEN.

Your body is made of lots of non-metals.

Two or more atoms stuck together form a substance called a molecule.

The OXYGEN atoms you breathe from the air always come in pairs, as molecules called O_2 .

HYDROGEN and OXYGEN together make water.

Pure CARBON comes in lots of shapes and forms.

An alchemist called Hennig Brand discovered a new non-metal in 1669.

NITROGEN and PHOSPHORUS compounds are used in plant fertilizers.

PHOSPHORUS is a crucial part of DNA – the chemical code that builds living things.

Animals need OXYGEN to survive.

OXYGEN is used in the chemical reaction that produces energy, inside animals' bodies.

Plants need a compound of CARBON and OXYGEN, called carbon dioxide, to survive.

When OXYGEN reacts with fuels such as wood or coal, and there's a spark...

The outside of the Earth is mostly made of non-metals. Lift the flap to see the elements inside the Earth.

Only one type of animal can survive without OXYGEN – microscopic sea creatures called loricifera.

Brazil nuts contain more SELENIUM than any other food.

SELENIUM can cause bad breath and smelly bodies.

Urgh!

Ew!

SULFUR is the smelliest element.

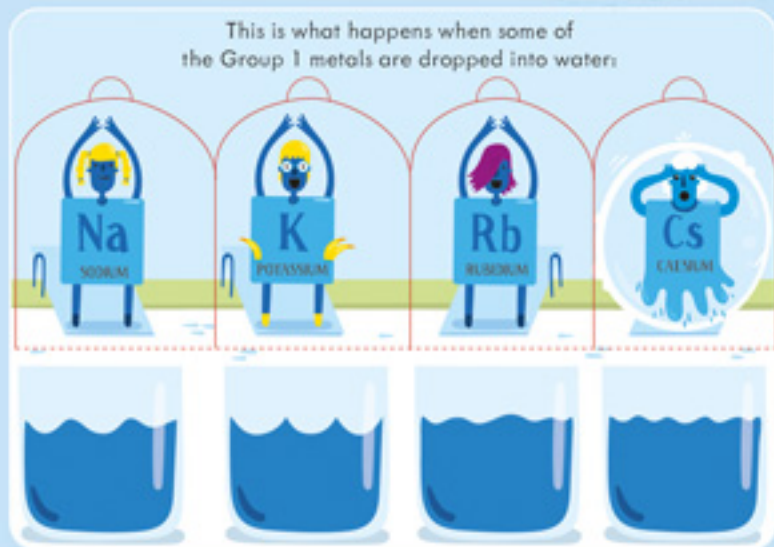

When HYDROGEN, SULFUR and OXYGEN combine...

Elements that FIZZ and BANG

The elements down the left two columns of the table are metals that fizz, flash, bang or explode when they come into contact with other elements. They're known as **reactive metals**.

When SODIUM reacts with the gas CHLORINE they turn into a compound called sodium chloride – also known as table salt.

There are lots of other types of salt too. Whenever a Group 1 or 2 metal reacts with a non-metal, they form a salt (but you can't eat them).

Here are some more of the reactive metals.

LITHIUM and BERYLLIUM were two of the first elements to exist in the Universe.

Tiny amounts of STRONTIUM in fossilized bones can tell archaeologists where that person lived and died.

CAESIUM is used to make night vision goggles.

RADIUM used to be used to paint glow-in-the-dark hands on watches and clocks.

If MAGNESIUM catches fire, hosing it with water...

OOO!

LITHIUM is a metal, but it's so soft you could cut it with a knife.

Nobody knows much about FRANCIUM, because it disappears almost immediately after being created.
